A Window into the Unseen

Neutrinoless double beta decay is a hypothetical process in which an atomic nucleus undergoes a transformation, releasing two electrons without emitting antineutrinos. This rare event, if it exists, would have profound

implications for our understanding of the universe, as it would violate a fundamental conservation law known as lepton number conservation.

The search for neutrinoless double beta decay has captivated the imagination of physicists for over half a century, driving the development of cutting-edge experimental techniques and theoretical frameworks. The discovery of this phenomenon would not only confirm the existence of Majorana neutrinos, particles that are their own antiparticles, but it would also open new avenues for exploring the nature of dark matter and the physics beyond the Standard Model.
